In this article, I would like to document how to set up a load balanced high availability standalone cluster.

For domain cluster refer to [WildFly 8 Clustering Howto \(WildFly 8 Clustering Howto.html\)](#).

## Preparation and Scenario

We need to prepare two hosts for this. We will assume that the following conditions are satisfied

- Two Nodes with \*Nix installed
- Make sure that they are in same local network
- Make sure that they can access each other via different TCP/UDP ports(better turn off firewall and disable SELinux during the experiment or they will cause network problems).

## Scenario

- We are going to install 2 standalone instances of WildFly - Let's call them Server One and Server Two
- Both servers execute the full-ha profile
- Apache httpd will be run on Server One and in httpd we will enable the mod\_cluster module. The WildFly 8 on both the servers will form a cluster and discovered by httpd.

## Download WildFly 8

First we should download WildFly 8 from the website:

```
$ wget http://download.jboss.org/wildfly/8.1.0.Final/wildfly-8.1.0.Final.tar.gz
```

Next untar the downloaded zip

```
mkdir ./wildfly;tar -xvf ~/wildfly-8.1.0.Final.tar.gz -C wildfly --strip-components=1
```

The above command will untar the package in to the wildfly directory

On changing to the wildfly directory and listing the directory structure, you should see the below structure

```
bash-4.1$ cd wildfly/
bash-4.1$ ls
appclient  bin  copyright.txt  docs  domain  jboss-modules.jar  LICENSE.txt  modules  README.txt  standalone  welcome-content
```

## Starting Wildfly in Cluster Configuration

Starting the wildfly instance can be done using the below command on Unix on both the servers

```
./standalone.sh -c standalone-ha.xml -b=$HOSTNAME -bmanagement=$HOSTNAME -u 230.0.0.4 -Djboss.node.name=$HOSTNAME
```

Here the -c option specifies the configuration file to use. We are going to use the High-Availability setup  
The -u option describes the multicast address. It is using this IP both servers communicate.  
For ease of setup, I have included the \$HOSTNAME in the nodename and start up options

For windows User, replace the \$HOSTNAME with %COMPUTERNAME%

Please note that you should be in wildfy/bin when you execute the above command

You should observe similar output

```
=====
JBoss Bootstrap Environment

JBOSS_HOME: /opt/app/wildfly

```

## Installing & Configuring Apache Httpd

### Download Apache httpd

Get the httpd from the JBoss download site:

```
wget http://downloads.jboss.org/mod_cluster//1.2.6.Final/linux-x86_64/mod_cluster-1.2.6.Final-linux2-x64.tar.gz
```

This version is pre-configured with all set up necessary to run mod\_cluster out of the box and connect with JBoss

If you already have HTTPD installed, then, please get the following archive and untar

```
wget http://downloads.jboss.org/mod_cluster//1.2.6.Final/linux-x86_64/mod_cluster-1.2.6.Final-linux2-x64-so.tar.gz
```

The httpd and it's associated configuration assumes that the server will be installed in /opt/jboss/httpd.

If you do not follow this path structure, then the configurations do not work.

On \*nix, you can use the ln command to create a symbolic link to /opt/jboss/httpd and configure as needed

Sample as listed below

```
/bin/ln -s /opt/app/myapp/httpd /opt/jboss/httpd
```

?

## Configuration

The main configuration for the server would be under the

```
$SERVER_ROOT/httpd/httpd/conf
```

?

Ensure the Listen directive is setup appropriately.

```
Listen 135.101.232.143:8081
```

?

At the end of the file ensure that the mod\_cluster directive are appropriately setup

```
<IfModule manager_module>
  Listen 135.101.232.143:6666
  ManagerBalancerName mycluster
  <VirtualHost 135.101.232.143:6666>
    <Location />
      Order allow,deny
      Deny from none
      Allow from 135.101.232.
    </Location>

    KeepAliveTimeout 300
    MaxKeepAliveRequests 0
    #ServerAdvertise on http://@IP@:6666
    AdvertiseFrequency 5
    #AdvertiseSecurityKey secret
    #AdvertiseGroup @ADVIP@:23364
    EnableMCPMReceive

  <Location /mod_cluster_manager>
```

?

(#)

```
        SetHandler mod_cluster-manager
        Order allow,deny
        #Deny from all
        Allow from all
    </Location>
    ProxyPass / balancer://mycluster/

</VirtualHost>
</IfModule>
```

Save and exit.

Now, execute Apache via the following command

```
/opt/app/jboss/httpd/sbin/apachectl -k start
```

Verify by opening the url: `http://<IP>:6666/mod_cluster_manager` in your browser

You should see something similar to this:

## mod\_cluster/1.2.6.Final
